Question:

A beam of light consisting of two wavelengths, 650 nm and 520 nm, is used to obtain interference fringes in a Young's double-slit experiment.

- (a) Find the distance of the third bright fringe on the screen from the central maximum for wavelength 650 nm.
- (b) What is the least distance from the central maximum where the bright fringes due to both the wavelengths coincide?

Solution: Consider single source interference. Let

Variable	Description	Value
<i>y</i> ₁	Wave Equation of First Wave	none
<i>y</i> ₂	Wave Equation of Second Wave	none
Y	Resultant Wave	none
f_c	Frequency of wave	none
A	Amplitude of Wave	none
λ_1, λ_2	Wavelengths	650,520
d	distance between the 2 slits	None
D	Distance from slits and Screen	None
TABLE 1		

VARIABLES AND THEIR VALUES

the wave equations of the 2 waves coming from λ source be y_1,y_2 . Assume an impulse emitted at source, travelling through the path labeled Wave 1 be t_1 and for travelling through path Wave 2 be t_2 respectively. The corresponding wave equations are

$$v_1 = A\sin(2\pi f_c t_1) \tag{1}$$

$$y_2 = A\sin(2\pi f_c t_2) \tag{2}$$

 t_2 can be written in terms of t_1 as

$$t_2 = t_1 + \Delta t \tag{3}$$

Where the term Δt arises because of paths chosen. the values of t_1, t_2 are

$$t_{1} = \frac{\sqrt{\left(\frac{d}{2} - b_{1}\right)^{2} + (a_{1})^{2}} + \sqrt{\left(\frac{d}{2} - y\right)^{2} + (D)^{2}}}{c}$$

$$t_{2} = \frac{\sqrt{\left(\frac{d}{2} + y\right)^{2} + (D)^{2}} + \sqrt{\left(\frac{d}{2} + b_{1}\right)^{2} + (a_{1})^{2}}}{c}$$

$$t_{3} = \frac{\sqrt{\left(\frac{d}{2} + y\right)^{2} + (D)^{2}} + \sqrt{\left(\frac{d}{2} + b_{1}\right)^{2} + (a_{1})^{2}}}{c}$$

$$t_{4} = \frac{\sqrt{\left(\frac{d}{2} + y\right)^{2} + (D)^{2}} + \sqrt{\left(\frac{d}{2} + b_{1}\right)^{2} + (a_{1})^{2}}}{c}$$

$$t_{5} = \frac{\sqrt{\left(\frac{d}{2} + y\right)^{2} + (D)^{2}} + \sqrt{\left(\frac{d}{2} + b_{1}\right)^{2} + (a_{1})^{2}}}{c}$$

$$t_{5} = \frac{\sqrt{\left(\frac{d}{2} + y\right)^{2} + (D)^{2}} + \sqrt{\left(\frac{d}{2} + b_{1}\right)^{2} + (a_{1})^{2}}}{c}$$

$$t_2 = \frac{\sqrt{\left(\frac{d}{2} + y\right)^2 + (D)^2} + \sqrt{\left(\frac{d}{2} + b_1\right)^2 + (a_1)^2}}{c}$$
(5)

Assuming the approximations

$$b_1 << a_1 \tag{6}$$

$$b_1 \sim d \tag{7}$$

$$d << D \tag{8}$$

$$(1+x)^n \simeq 1 + nx \tag{9}$$

We get

$$\Delta t = \frac{\frac{db_1}{a_1} + \frac{dy}{D}}{c} \tag{10}$$

On substituting t_2 in (2) and applying superposition theorem, we get

$$Y = y_1 + y_2 (11)$$

$$Y = 2A \sin\left(2\pi f_c \left(t_1 + \frac{\Delta t}{2}\right)\right) \cos\left(2\pi f_c \left(\frac{\Delta t}{2}\right)\right)$$
 (12)

For constructive interference

$$f\Delta t = n \tag{13}$$

substituting in (10), we get

$$\frac{db_1}{a_1} + \frac{dy}{D} = n\lambda \tag{14}$$

The equation (14) is the condition for constructive interference. For 2 sources, we do it as follows. From Fig. 2,

$$\frac{db_1}{a_1} + \frac{dy}{D} = n_1 \lambda_1 \tag{15}$$

$$\frac{db_2}{a_2} + \frac{dy}{D} = n_2 \lambda_2 \tag{16}$$

Now, for lights from both sources to interfere at a point constructively,

$$n_1 \lambda_1 = n_2 \lambda_2 \tag{17}$$

(a) From Table 1 and (14), taking $b_1 = 0$

$$n_1 = 3 \tag{18}$$

$$y = \frac{n_1 \lambda_1 D}{d} \tag{19}$$

$$y = 1950 \frac{D}{d} \tag{20}$$

(b) From Table 1, (14), (17) and taking $b_1 = 0$, $b_2=0$

$$n_1 \lambda_1 = n_2 \lambda_2 \tag{21}$$

$$\frac{n_2}{n_1} = \frac{\lambda_1}{\lambda_2} = \frac{650}{520} \tag{22}$$

$$\frac{n_2}{n_1} = \frac{\lambda_1}{\lambda_2} = \frac{650}{520}$$

$$\frac{n_2}{n_1} = \frac{5}{4}$$
(22)

Now we can assume $n_2 = 5k$ and $n_1 = 4k$ where k is some positive integer. For smallest value of y we shall take k = 1.

$$y = \Delta x_1 \frac{D}{d} = 2600 \frac{D}{d} nm \tag{24}$$
